

Conductive Thermoplastic Polymer Composites for Road Infrastructure

S. Mamulat • K. Prokopovich • I. Burmistrov •
Plekhanov Russian University of Economics • NUST MISIS

Motivation: Winter Maintenance Has Hidden Costs

De-icing salts

Mechanical clearing

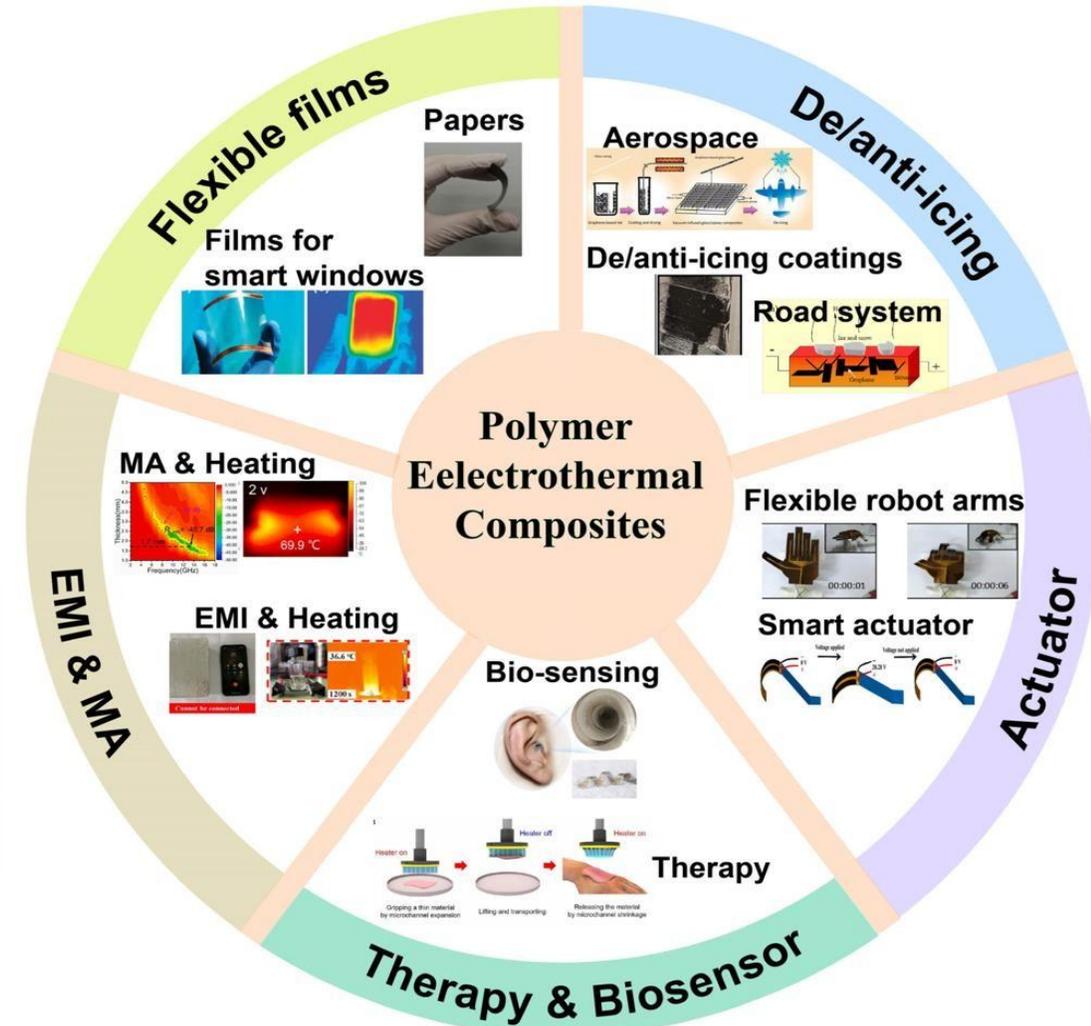

Why alternatives matter

- Salts accelerate corrosion of infrastructure and vehicles
- Chemical runoff harms the environment
- Freeze–thaw + chemicals increase pavement degradation and maintenance cost

Proposed Solution: Conductive Thermoplastic Composites

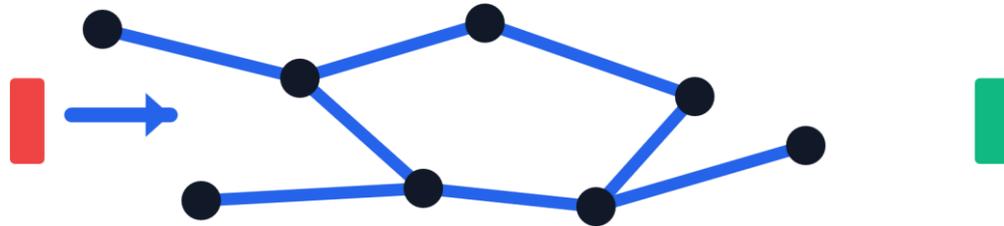

A single functional layer can:

- Generate heat (Joule heating) to prevent icing / melt snow
- Sense traffic loads via piezoresistive response
- Enable rapid repair/rewelding thanks to thermoplastic matrix
- Support retrofit installation on critical segments (bridges, ramps)

How It Works: Percolation + Joule Heating + Sensing

1) Conductive network (percolation)

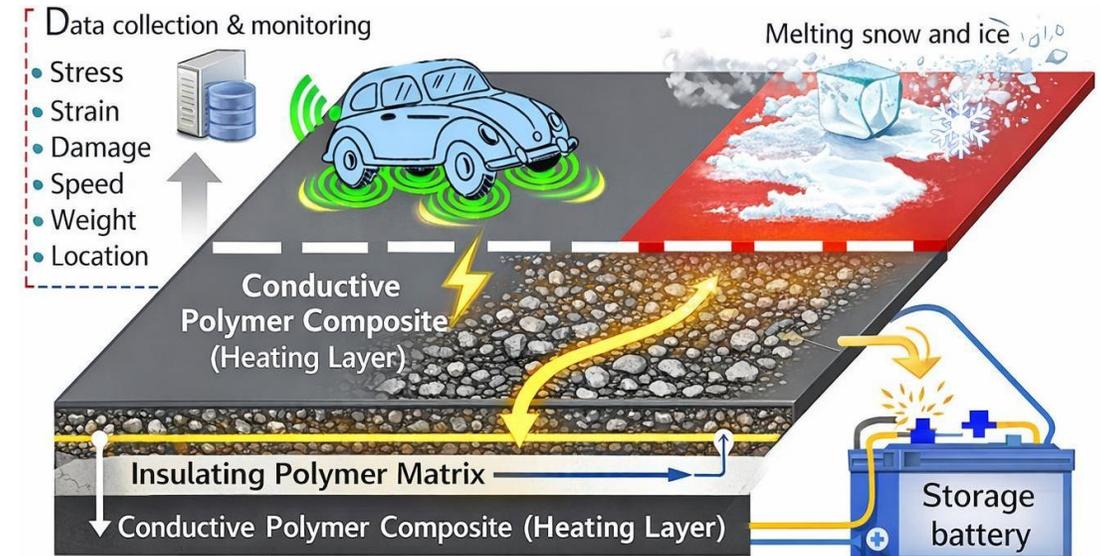

2) Joule heating ($Q = I^2 * R * t$)

Heat is generated in the conductive pathway, weakening ice adhesion and melting snow.

3) Piezoresistive sensing

Under load, the network changes → resistance changes (strain/weight sensing).

Data Collection & Monitoring

- Stress
- Strain
- Damage

Self-Healing & Energy Harvesting

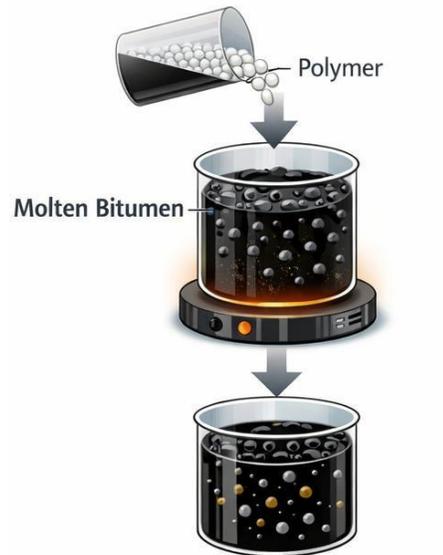

Smart road surface scheme

Thermoplastics + bitumen: two routes

Wet Modification

Polymer added directly to bitumen

Polymer Modified Bitumen

Wet modification

Polymer blended into the binder (typical dosages depend on binder & polymer)

Dry Modification

Polymer added to asphalt mix in solid form

Polymer Modified Asphalt

Dry modification

Polymer added as solid to asphalt mix; requires good dispersion & mixing control

Methods of self-healing of road surfaces

Thermal Healing

- ✓ Easy principle
- ✗ Significant energy demand
- ✗ Limited repair depth
- ✗ Uneven heating

Benefits:

- ✓ Easy principle

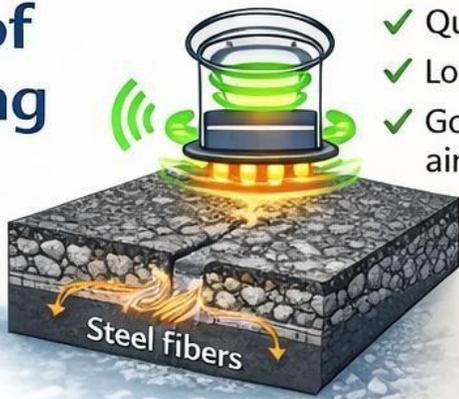

Methods of Self-Healing Asphalt

Induction Heating

- ✓ Quick repair
- ✓ Localized smart control
- ✓ Good for bridges and airfields

Challenges:

- Requires special equipment
- ✗ Weight and cost of steel particles

Microwave / RF Heating

- ✓ Fast, deep heating
- ✓ Works for asphalt and composites

Challenges:

- Needs radiation-safe equipment

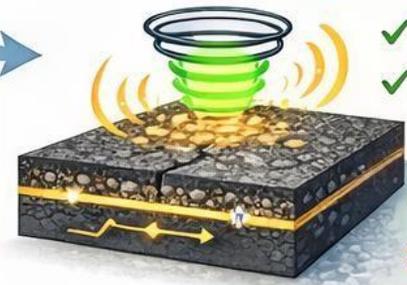

Conductive Composites

- ✓ Precise heating control
- ✓ Multiple functions (eg, sensing, anti-icing) in one layer

Challenges:

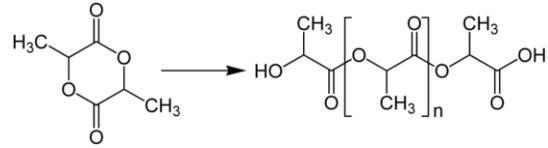

- ✗ Avoid filler degradation
- ✗ Energy / salt / moisture exposure

- ✓ Microwave / RF Heating
- ✓ Fast, deep heating
- ✓ Works for asphalt and composites

- ✓ Temperature-based heating
- Multiple functions (e.g., sensing, anti-icing) in one layer
- ✗ Avoid filler degradation
- ✗ Energy / salt / moisture exposure

Why PLA (polylactide)?

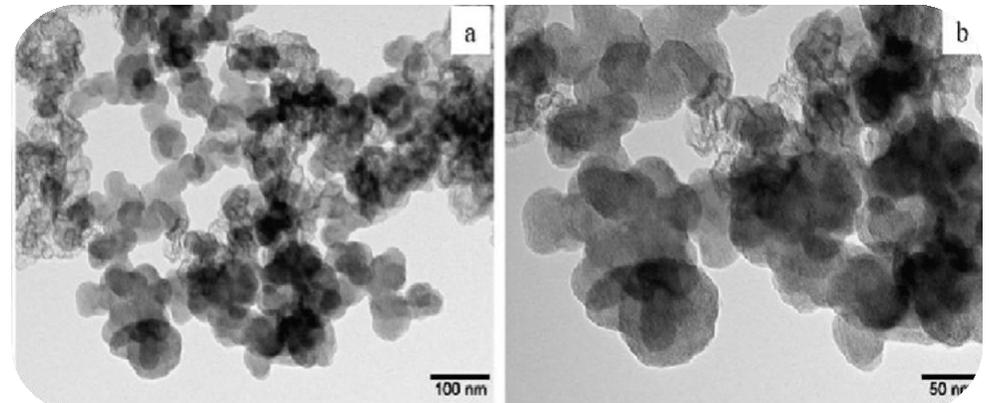

- Thermoplastic: easy processing, welding and repair by reheating
- High stiffness/strength among biopolymers (reported $E \approx 3.5$ GPa, $\sigma_t \approx 50$ MPa)
- Renewable feedstocks; biodegradable mainly under industrial composting conditions

Why carbon black (Printex XE-2B)?

- Forms percolation network at moderate loadings
- Cost-effective vs CNTs/graphene/silver
- Potential to use recovered carbon black from waste streams (e.g., tires)

Pellet feedstock (illustrative)

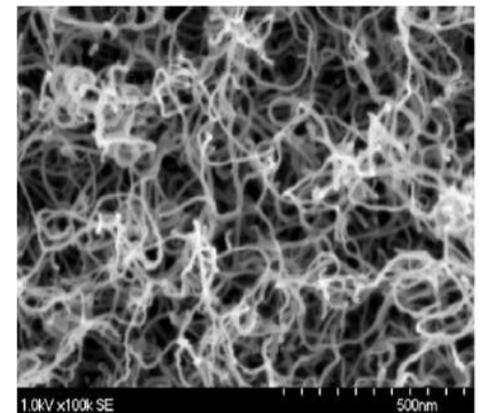

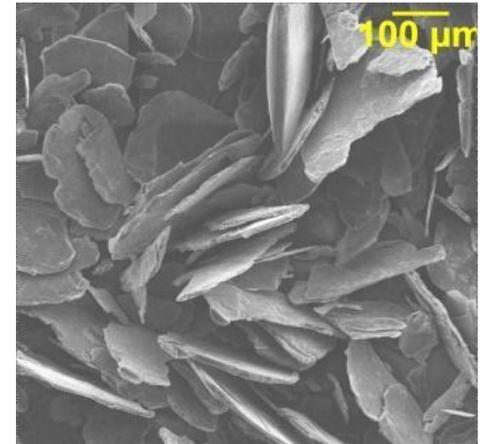

Carbon black microstructure (TEM)

Why Carbon Black: Cost Advantage vs Other Conductive Fillers

Representative prices

Filler	Indicative price / kg
Carbon black (PRINTEX® XE 2B)	≈ \$2.6
Battery carbon black (Super-P Li)	\$25–35
Industrial CNTs	\$199–450
MWCNTs (lab packaging)	\$600–25,000
Graphene nanoplatelets	\$500–25,000
Silver powder	€1,520

Technological and performance additives: plasticizers

Propylene carbonate (PC)

Ethylene vinyl acetate copolymer (EVA)

Goal:

Improve conductivity while keeping mechanical performance suitable for a functional pavement layer.

Formulations (all with 10 wt.% carbon black)

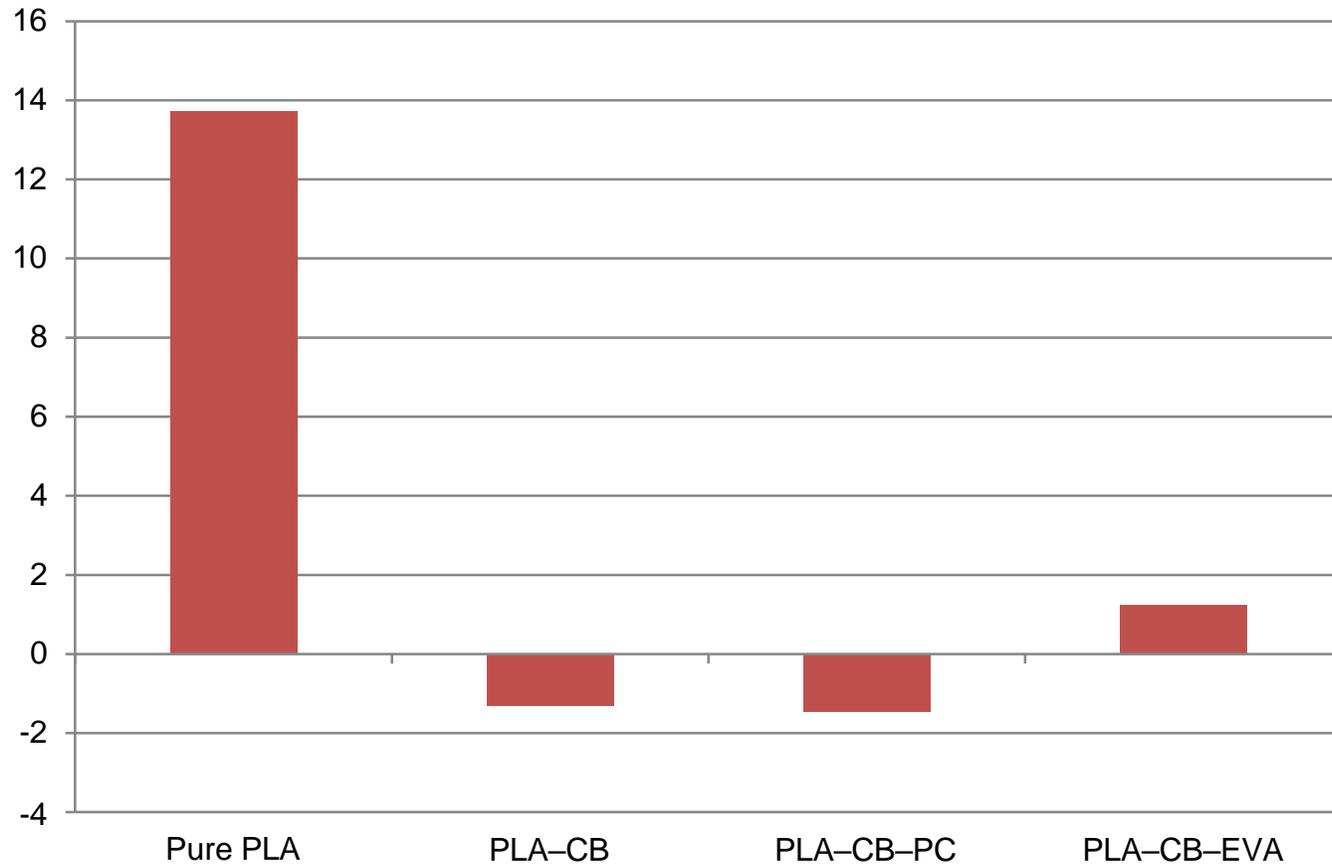

- Pure PLA (baseline)
- PLA–CB (10 wt.% CB)
- PLA–CB–PC (20% propylene carbonate plasticizer)
- PLA–CB–EVA (20% ethylene–vinyl acetate copolymer)

Measurements

- Electrical: 4-point probe on a Jandel RM3000 (Jandel Engineering, UK) (ρ , $\Omega\cdot\text{m}$)
- Mechanical: tensile tests a universal testing machine GP UG 5 DLC-0,5 DVT (DEVOTRANS, Turkey) per ISO 527-1 / ISO 527-3 (50 mm/min)

Electrical Performance: Percolation Achieved at 10 wt.% CB

Specific volume resistivity (\log_{10} scale, $\Omega\cdot\text{m}$)

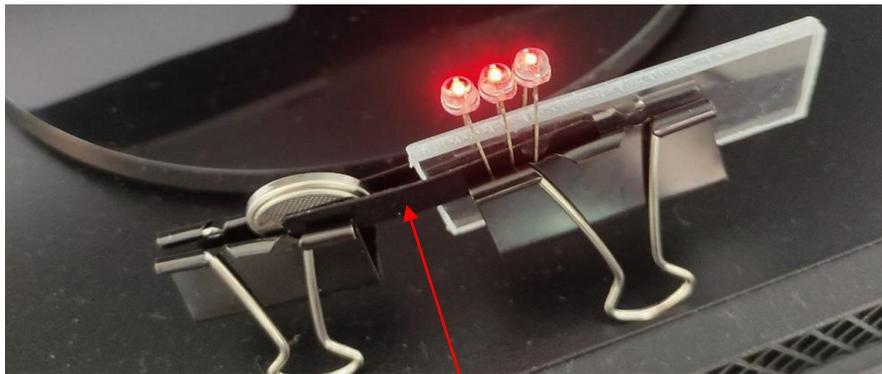

ρ ($\Omega\cdot\text{m}$): PLA 5.2×10^{13} • PLA-CB 0.049 • +PC 0.035 • +EVA 17.88

Key observations

- Adding 10 wt.% CB drops resistivity by ~ 15 orders of magnitude vs pure PLA
- Propylene carbonate (PC) slightly improves conductivity
- EVA plasticizer dramatically increases resistivity

Specific volume resistivity (\log_{10} scale, $\Omega\cdot\text{m}$)

Composition title	PLA, wt. %	CB, wt. %	ρ , $\Omega\cdot\text{m}$
Pure PLA	100	0	$5,20 \times 10^{13}$
PLA-CB	90	10	0,049
PLA-CB-PC (20% of plasticizer)	70	10	0,035
PLA-CB-EVA (20% of plasticizer)	70	10	17,880

The resulting PLA-CB-PC composite

Key observations

- Adding 10 wt.% CB drops resistivity by ~ 15 orders of magnitude vs pure PLA
Propylene carbonate (PC) slightly improves conductivity further
EVA plasticizer dramatically increases resistivity

Tensile properties (ISO 527)

Composition title	Modulus, MPa	Strength, MPa	Elongation, %
Pure PLA	2310,05	88,95	3,97
PLA-CB	2900,30	30,05	2,81
PLA-CB-PC (20% of plasticizer)	289,22	10,71	58,33
PLA-CB-EVA (20% of plasticizer)	2310,50	17,47	3,36

Interpretation

- CB increases stiffness but reduces strength vs pure PLA
CB plasticizer yields very high ductility ($\approx 58\%$ elongation) but greatly reduces modulus/strength
EVA keeps modulus closer to PLA but conductivity suffers (see Slide 10 & 11)

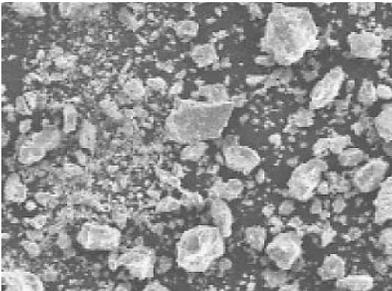

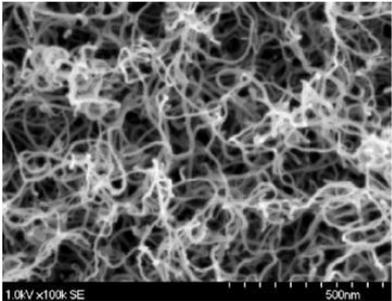

Basic principles of modifying the composition of a bituminous binder for microwave-induced

Production of asphalt concrete based on modified bitumen, production of road surface

Bitumen

nanodisperse modifiers

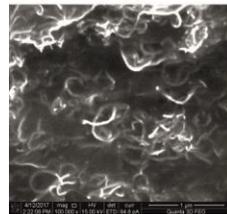

High-energy processing
(ultrasonic, microwave)

Self-healing of defects and restoration of the road surface without replacing the wear layer

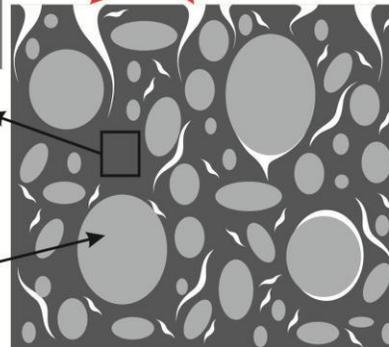

nanomodified bituminous binder

microwave-resistant filler

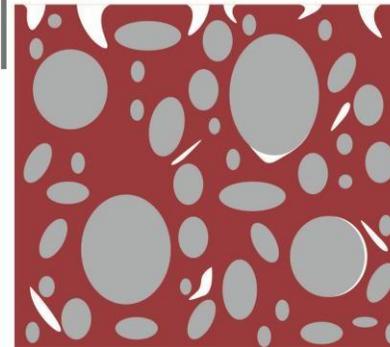

modified asphalt concrete

micro-defects in the road surface

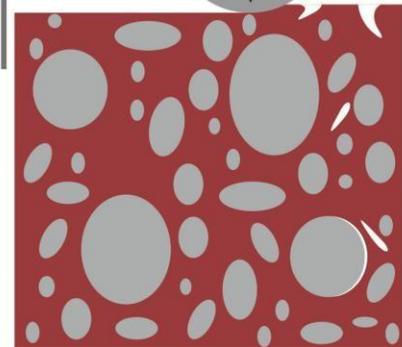

Microwave (induction-) induced volumetric heating

Microwave

mechanical impact (asphalt rolling)

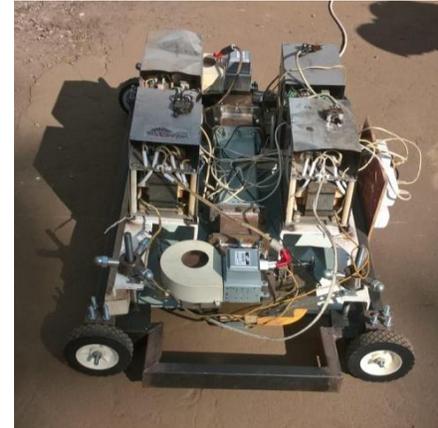

The principle of microwave-induced self-healing and restoration of the road surface wear layer

Conventional wheel roller

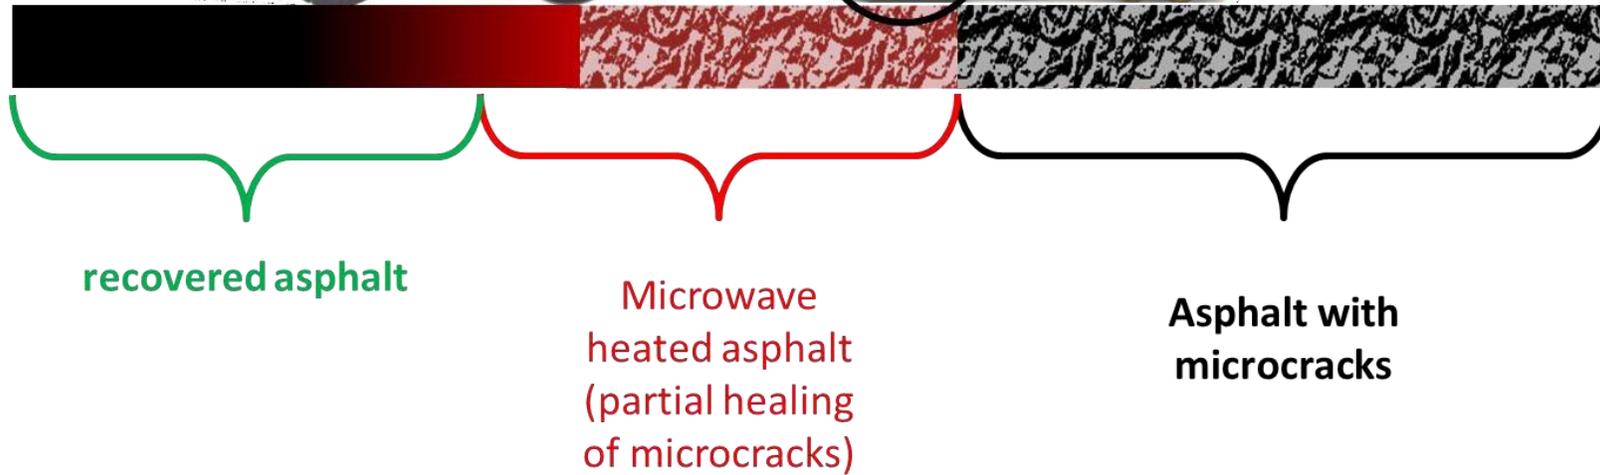

Microwave heater machine

Experimental prototype

An experimental prototype

Key Takeaways

- PLA + 10 wt.% carbon black achieves electrical percolation ($\rho \sim 10^{-2} \Omega \cdot \text{m}$ range)
- Propylene carbonate improves conductivity and ductility, but strongly softens the material
- EVA plasticizer degrades conductivity (not preferred for electro-heating)
- Concept enables multi-function pavement: anti-icing + sensing, with thermoplastic repairability

Next steps: durability under traffic & freeze–thaw, moisture/UV protection, and power optimization.

Thank you!
